

# A number, like any other tool gives you

Financed emissions for a lending book. Every carbon tool on the market can produce this figure. None of them can tell you what it rests on.

# 37,500

TCO<sub>2</sub>E · SCOPE 3 CATEGORY 15 · CORPORATE LENDING

# Click it, and the working opens

Not a tooltip. The actual arithmetic, with the factor that produced it named.

```
$250mn × 150 t/$mn = 37,500.00 tCO2e
```

|        |                                                |
|--------|------------------------------------------------|
| LINE   | PCAF corporate lending · WACI                  |
| METHOD | Attribution, weighted average carbon intensity |

# The factor names its own source

Value, unit, basis, region, vintage, confidence — from a register that is published, versioned, and built deterministically.

|            |                                  |           |
|------------|----------------------------------|-----------|
| FACTOR     | Corporate lending — WACI default | UNSOURCED |
| APPLIED    | 150 tCO <sub>2</sub> e / USD mn  |           |
| SOURCE     | Not established                  |           |
| VINTAGE    | —                                |           |
| CONFIDENCE | Low                              |           |

We could not source this figure. Rather than quietly ship a number that looks authoritative, the register says so — here, and in every document it reaches.

## So the line is scored, and told why

Every emission line gets a data quality tier, derived from evidence the system already holds. Nothing extra is asked of you.

|           |                                                                    |
|-----------|--------------------------------------------------------------------|
| TIER      | 4 of 5 <b>WEAK</b>                                                 |
| BECAUSE   | The factor is low confidence and its provenance is not established |
| INVENTORY | 4.1 of 5, emissions-weighted across every line                     |

A line takes the worst tier among the factors behind it — the reading an assurance provider would take.

# The ledger ranks it against everything else

Not by how bad the tier is. By how much of your inventory is sitting on it.

- |   |                                                     |
|---|-----------------------------------------------------|
| 1 | PCAF corporate lending · WACI 37,500 t · 72% · DQ 4 |
| 2 | Use of sold products 6,444 t · 12% · DQ 5           |
| 3 | Purchased goods & services 6,300 t · 12% · DQ 4     |
| 4 | Waste to landfill 65 t · 0.1% · DQ 4                |

Waste is also tier 4. It is a rounding error. Sorting by severity would have put it beside the number carrying the whole report.

# And the pack tells your auditor first

One document, assembled from the register and the ledger. It computes its own limitations rather than presenting only strengths.

SECTION 3      Emission factors applied — 7 rows, 2 flagged unsourced

SECTION 5      Gaps, largest first

SECTION 6      Audit trail, every line with its calculation

SECTION 7      "2 of the 7 factors applied have no establishable source"

**That sentence is computed, not written.** A pack that presents only strengths is the one an auditor distrusts. Your data never leaves the browser to produce any of this.
